

Interpretation of Organic Data

Roy-Keith Smith, PhD

January, 2000

Contents

Figures

Tables

Introduction/Preface

1. Separation and Sample Preparation

Analyte isolation and concentration

Resolution

Matrix interferences

2. Detection

3. Compound Identification

Calibrated compounds

Two-dimensional detectors

Three-dimensional detectors

Tentatively Identified Compounds

4. Quantitation

Definition and determination of analyte response

Technique of Calibration

External standard calibration

Internal standard calibration

Initial and continuing calibration verification

Boundaries of calibration

Visual evaluation of calibrations

Product analysis

5. Quality Control Acceptance limits

6. Instrument Quality Control

Tuning

System Performance

Maintenance Records

7. Laboratory Contamination

Blanks

Phthalate Contamination

Methylene Chloride Contamination

Acetone Complex

Blanks in the Volatiles Laboratory

Laboratory Contaminants That Aren't

Other Contaminant Indicators

8. Assessing Target Analyte Recovery

Surrogates

Matrix Spikes and Laboratory Control Sample

9. Other Data Assessments

Holding times and temperature preservation

Laboratory documentation

- 6-3 Endrin and it's two breakdown products
- 6-4 Chromatogram of a breakdown evaluation
- 6-5 Tailing factor measurements and calculation
- 7-1 Control chart of bis(2-ethylhexyl)phthalate contamination levels. Units are ng/uL injected on-column
- 7-2 Control chart for dibutylphthalate in blanks. Units are ng/uL on-column
- 8-1 Chromatogram exhibiting a significant interference

Tables

- 1-1 Structural isomers of hexane
- 1-2 Organic semivolatile sample preparation and clean-up procedures in SW-846
- 3-1 A partial listing of the compounds that can co-elute with benzene during analysis with a GC-PID
- 4-1 Example of an audit trail file
- 4-2 Calibration data for peak #1 of Arochlor 1016
- 4-3 Calibration data for peak #1 of Arochlor 1016 (Table 4-2) with two additional points.
- 7-1 The list of usual suspects found as laboratory contamination
- 8-1 VOC target analyte (EPA Method 8260B) elution orders
- 8-2 BNA target analyte (EPA Method 8270C) elution order
- 8-3 Chlorinated pesticide target analyte (EPA Method 8081A) elution order
- 8-4 Chlorinated acid herbicide target analyte (EPA Method 8151A) elution order
- 8-5 Nitrogen-phosphorus pesticide target analyte (EPA method 8141A) elution order.
- 8-6 Historical surrogate recovery limits for water samples processed by EPA Method 3510/8270 with K-D concentration from a laboratory as compared to literature values for the sample matrix and methods
- 8-7 Characteristic 8270 surrogate recovery patterns for different situations
- 8-8 Common surrogate patterns from diluted samples
- 9-1 Theoretical dependence of storage temperature on holding time (nominally 28 days at 4C)

Introduction and Preface

I have in other books¹ tried to present in considerable detail the requirements for acceptable analysis of environmental samples. I have divided these requirements into the categories of analytically valid and legally defensible, and spent about equal time writing on each. The term “evaluation” has been used to mean analytical worth of data and “validation” to describe the legal compliance side. However in practice what I have noticed in the environmental industry is that some persons who review data tend to spend a lot more time on the legal acceptability rather than the analytical utility of results. There are many reasons for this. It’s easier to know and apply the dictates of “thou shall” and “thou shall not”. Validation of results for these dictates tend to be more of a book keeping exercise and I may have been as guilty as any other in drawing attention to this essential component of data acceptability.

The Environmental Protection Agency (EPA) is currently in the process of debating and adopting the Performance Based Measurement System (PBMS) as a paradigm for environmental analysis. In PBMS good science is stressed. This places an extra burden on persons reviewing data as they have to be able to recognize what is good science and what is not. My attempt in this book is to describe what is good science and what is not within the context of organic analysis under PBMS.

I have characterized this business as frequently frustrating but never boring. Every person I have ever met in this business has taught me something. The something may be positive or it may be negative, and in some cases it is accompanied by tense situations, but still my fund of knowledge grows. As always my thanks go out to my editor, Erik Roy at Genium, the owners of Analytical Services, Inc., Robert G. Owens, Jr, G. Wyn Jones, and Billy Paul Dyer, and all the colleagues, peers, and data reviewers with whom I interact in the environmental industry. I am not going to try to list them all, as someone might be slighted that they got overlooked. But if I have ever met you, and this includes all those who I have ever disagreed with, thanks.
